## Circuit Description

This circuit is intended for driving high power LEDs, such as the Cree XLAMP ${ }^{\text {тм }}$ series, Lumileds Luxeon ${ }^{\text {™ }}$ Rebel and K2 and OSRAM, Golden and Platinum Dragon ${ }^{\text {TM }}$ as well as the OSTAR ${ }^{\text {TM }}$. It is designed for such wide input nominal 12 Vdc applications as automotive and low voltage lighting (12 $\mathrm{Vdc} / 12 \mathrm{Vac}$ ). An optional dimming PWM input is included. The circuit is based on NCP3065 operation at 250 kHz in a non-isolated configuration. The primary advantages of this circuit are in the wide input voltage range, wide output voltage range, and in its high efficiency.

A pulse feedback resistor (R8) is used to vary the slope of the oscillator ramp, achieving duty cycle control and steady switching frequency over a wide input voltage range.

## Key Features

- Buck-Boost operation
- Wide input and output operation voltage
- Regulated output current
- Dimming
- High frequency operation
- Minimal input and output current ripple
- Open LED protection
- Output short circuit protection

Schematic

Figure 1 - SEPIC converter schematic

## Design Notes

A SEPIC (single-ended primary inductance converter) is distinguished by the fact that its input voltage range can overlap the output voltage range. The basic schematic is shown in Figure 2.

Figure 2 - Generalized SEPIC schematic
When switch SW is ON, energy from the input is stored in inductor L1. Capacitor CP is connected in parallel to L2, and energy from CP is transferred to L2. The voltage across L2 is the same as the CP voltage, which is the same as the input voltage. At this time, the diode is reverse biased and COUT supplies output current.

If the switch SW is OFF, current in L1 flows through CP and D1 then continues to the load and COUT. This current recharges CP for the next cycle. Current from L2 also flows through D1 to the load and COUT that is recharging for the next cycle.

Inductors L1 and L2 could be uncoupled, but then they must be twice as large as if they are coupled. Another advantage is that if coupled inductors are used there is very small input current ripple.

Values of coupled inductors are set by these equations:

$$
\begin{gathered}
D=\frac{V_{\text {OUT }} \min }{V_{\text {OUT }} \min +V_{I N} \min }=\frac{7.2}{7.2+8}=0.47 \\
\Delta I=r \cdot I_{\text {OUT }} \frac{D}{1-D}=0.8 \cdot 0.7 \cdot \frac{0.47}{1-0.47}=0.51 \mathrm{~A} \\
L_{1,2}=\frac{V_{\text {IN }} \min \cdot D}{2 \cdot f \cdot \Delta I}=\frac{8 \cdot 0.47}{2 \cdot 250 \cdot 10^{3} \cdot 0.51}=15.0 \mu \mathrm{H}
\end{gathered}
$$

where $r$ is the maximum inductor current ripple factor.

## DN06031/D

For a 0.35 A output current variant of this circuit, the values of inductors are

$$
\begin{aligned}
& \Delta I=r \cdot I_{\text {OUT }} \frac{D}{1-D}=0.95 \cdot 0.35 \cdot \frac{0.47}{1-0.47}=0.3 \mathrm{~A} \\
& L_{1,2}=\frac{V_{\text {IN }} \min \cdot D}{2 \cdot f \cdot \Delta I}=\frac{8 \cdot 0.47}{2 \cdot 250 \cdot 10^{3} \cdot 0.3}=25.1 \mu \mathrm{H}
\end{aligned}
$$

The nearest coupled inductor value for the 0.7 A variant is $15 \mu \mathrm{H}$. A variant with 0.35 A output current needs to use inductors with value $22 \mu \mathrm{H}$.

The output current is set by R10 (R11). So this resistor can be calculated by the formula:

$$
R 10=\frac{0.235}{I_{\text {OUT }}}=350 \mathrm{~m} \Omega .
$$

To protect the circuit against high output voltage under light loads or a fault condition, the output voltage is clamped by a Zener diode (D3) to approximately 24.5 V . Capacitor C7 is used to stabilize feedback, but it impacts line regulation. R3 fixes the line regulation error caused by C7.

External power MOSFET is driven by internal NPN Darlington transistor, external diode D2 and PNP transistor Q2. Compensated divider C3, R6 and R7 is used to reduce gate-source voltage, mainly for high input voltage and to keep sharp edges. Maximum gate-source voltage can be calculated by this formula:

$$
V_{G S} \max =\left(V_{I N}-V_{C E}-V_{D 2}\right) \cdot \frac{R 7}{R 6+R 7}=(27-1.4-0.4) \cdot \frac{1500}{390+1500}=18.4 V
$$

Maximum MOSFET current can be calculated in this way:

$$
I_{\text {Q4 } \max }=\left(1+\frac{r}{2}\right) \cdot I_{\text {OUT }} \frac{V_{\text {OUT }} \max }{V_{I N} \min }=\left(1+\frac{0.8}{2}\right) \cdot 0.7 \cdot \frac{23}{8}=2.5 \mathrm{~A}
$$

To minimize power MOSFET conductance losses, it is recommended to select a transistor with small $\mathrm{R}_{\mathrm{Dson}}$. To minimize switching losses, it is recommended to select a transistor with small gate charge. Power MOSFET must also have a breakdown voltage higher than:

$$
V_{\text {FETPK }}=V_{\text {IN }}+V_{\text {OUT }}=18+23=41 \mathrm{~V}
$$

Cycle by cycle switch current protection is set by R1 at

$$
I_{P K \text { set }}=\frac{0.2}{R 1}
$$

A suitable value is higher than maximum switch current.

$$
R 1<\frac{0.2}{I_{Q 1_{\max }}}=\frac{0.2}{2.5}=80 \mathrm{~m} \Omega
$$

Diode D1 maximum voltage is determined by this equation:

## DN06031/D

$$
V_{D 1 \max }=V_{I N}+V_{\text {OUT }}=18+23=41 \mathrm{~V}
$$

and with current

$$
I_{D 1}=I_{O U T}=0.7 \mathrm{~A}
$$

The C4 coupling capacitor is selected based on input voltage and on current

$$
\begin{gathered}
D \max =\frac{V_{\text {OUT }} \max }{V_{\text {OUT }} \max +V_{\text {IN }} \min }=\frac{23}{23+8}=0.74 \\
I_{\text {C4RMS }}=\frac{V_{\text {OUT }} \cdot I_{\text {OUT }}}{V_{\text {IN }}} \sqrt{\frac{1-D \max }{D \max }}=\frac{23 \cdot 0.7}{8} \sqrt{\frac{1-0.74}{0.74}}=1.2 \mathrm{~A}
\end{gathered}
$$

and its minimal value is

$$
C 4>\frac{I_{\text {OUT }} \cdot D \min }{0.05 \cdot V_{I N} \min \cdot f}=\frac{0.7 \cdot 0.47}{0.05 \cdot 8 \cdot 250 \cdot 10^{3}}=2 \mu F
$$

The output capacitor's current is

$$
\begin{gathered}
I_{\text {C5 }}=I_{\text {OUT }} \cdot \sqrt{\frac{D \max }{1-D \max }}=0.7 \sqrt{\frac{0.74}{1-0.74}}=1.2 \mathrm{~A} \\
C 5> \\
\frac{\frac{V_{\text {OUT }} \min }{V_{I N} \min } \cdot I_{\text {OUT }} \cdot D \min }{f \cdot r \cdot V_{\text {OUT }} \min }=\frac{\frac{7.3}{8} \cdot 0.7 \cdot 0.47}{250 \cdot 10^{3} \cdot 0.1 \cdot 7.3}=1.7 \mu \mathrm{~F}
\end{gathered}
$$

The value could be much larger for higher stability, but a higher value impacts the dimming function at low duty cycle.

The resistor R8 is used to stabilize feedback loop. Used value is compromise for whole input and output voltage range. If this circuit is used for specified load only, it should be tuned by this resistor to better efficiency and line regulation.

X1-3 input is used for dimming. The dimming signal level is $2-10 \mathrm{~V}$. The recommended dimming frequency is about 200 Hz . For frequencies below 100 Hz the human eye will see the flicker. The dimming function utilizes the NCP3065's peak current protection input. The second way to achieve this is to use the FB pin. See figure 10.

## Conclusion

This circuit is ideal in applications with strings of two to six LED chips powered from a power supply with wide input range ( $8-20 \mathrm{~V}$ ). The advantages of this circuit include its small size, low price, wide input and output voltage ranges, and very small input current ripple.
